## Abstract

We prove two results on the stability spectrum for  $L_{\omega_1, \omega}$ . Here  $S_i^m(M)$  denotes an appropriate notion (at or mod) of Stone space of  $m$ -types over  $M$ . Theorem A. Suppose that for some positive integer  $m$  and for every  $\alpha < \delta(T)$ , there is an  $M \in \mathbf{K}$  with  $|S_i^m(M)| > |M|^{\beth_{\alpha}(|T|)}$ . Then for every  $\lambda \geq |T|$ , there is an  $M$  with  $|S_i^m(M)| > |M|$ . Theorem B. Suppose that for every  $\alpha < \delta(T)$ , there is  $M_\alpha \in \mathbf{K}$  such that  $\lambda_\alpha = |M_\alpha| \geq \beth_\alpha$  and  $|S_i^m(M_\alpha)| > \lambda_\alpha$ . Then for any  $\mu$  with  $\mu^{\aleph_0} > \mu$ ,  $\mathbf{K}$  is not  $i$ -stable in  $\mu$ . These results provide a new kind of sufficient condition for the unstable case and shed some light on the spectrum of strictly stable theories in this context. The methods avoid the use of compactness in the theory under study. In the Section 4, we expound the construction of tree indiscernibles for sentences of  $L_{\omega_1, \omega}$ . Further we provide some context for a number of variants on the Ehrenfeucht-Mostowski construction.

## 1 Context

For many purposes, e.g., the study of categoricity in power, the class of models of a sentence  $\phi$  of  $L_{\omega_1, \omega}$  can be profitably translated to the study of the class of models of a first order theory  $T$  that omit a collection  $\Gamma$  of first order types over the empty set. In particular, if  $\phi$  is complete (i.e. a Scott sentence)  $\Gamma$  can be taken as the collection of all non-principal types and the study is of the atomic models of  $T$ . This translation dates from the 60's; it is described in detail in Chapter 6 of [Bal09]. The study of finite diagrams (see below) is equivalent to studying sentences of  $L_{\omega_1, \omega}$ ; the study of atomic models of a first order theory is equivalent to studying *complete* sentences of  $L_{\omega_1, \omega}$ .

---

\*We give special thanks to the Mittag-Leffler Institute where this research was conducted. This is paper F997 in Shelah's bibliography. Baldwin was partially supported by NSF-0500841. Shelah thanks the Binational Science Foundation for partial support of this research.

The stability hierarchy provides a crucial tool for first order model theory. Shelah [She78] and Keisler [Kei76] show the function  $f_T(\lambda) = \sup\{|S(M)| : |M| = \lambda, M \models T\}$  has essentially only six possible behaviors (four under GCH). In [She70], Shelah establishes a similar result for *homogeneous* finite diagrams. The homogeneity assumption is tantamount to assuming amalgamation over all sets. This is a strong hypothesis that is avoided in Shelah's further investigation of categoricity in  $L_{\omega_1, \omega}$  ([She83a, She83b]), which is expounded as Part IV of [Bal09]. Important examples, due to Marcus and Zilber, which do not satisfy the homogeneity hypothesis are also described in [Bal09]. As we explain below, this investigation begins by identifying the appropriate notion of type over a set (and thus of  $\omega$ -stability). Shelah [She83a, Bal09] showed that  $\omega$ -stability implies stability in all powers. And assuming  $2^{\aleph_0} < 2^{\aleph_1}$ ,  $\omega$ -stability was deduced from  $\aleph_1$ -categoricity. But further questions concerning the stability hierarchy for this notion of type for arbitrary sentences of  $L_{\omega_1, \omega}$  had not been investigated. We do so now. In fact our results hold for *arbitrary finite diagrams*, the class of models of first order theory that omit a given set of types over the empty set. But our results are by no means as complete as in homogeneous case.

There are (at least) two *a priori* reasonable notions of Stone space for studying atomic models of a first order theory. (As noted, we could more generally replace 'atomic' by 'finite diagram'.) Recall that for a first order theory  $T$  (with a monster model  $\mathbb{M}$ )  $A \subset \mathbb{M}$  is an *atomic set* if each finite sequence from  $A$  realizes a principal type over the empty set. An atomic set is an *atomic model* if it is also a model of the theory  $T$ .

**Definition 1.1** *Let  $\mathbf{K}$  be the class of atomic models of a complete first order theory.*

1. *Let  $A$  be an atomic set;  $S_{\text{at}}(A)$  is the collection of  $p \in S(A)$  such that if  $\mathbf{a} \in \mathbb{M}$  realizes  $p$ ,  $A\mathbf{a}$  is atomic.*
2. *Let  $A$  be an atomic set;  $S_{\text{mod}}(A)$  is the collection of  $p \in S(A)$  such that  $p$  is realized in some  $M \in \mathbf{K}$  with  $A \subseteq M$ .*

In [Bal09] we write  $S^*$  for the notion called  $S_{\text{mod}}$  here. The latter notation is more evocative. We will simultaneously develop the results for both notions of Stone space and indicate the changes required to deal with the two cases. We will write  $S_i(M)$  where  $i$  can be either at or mod.

We sometimes write  $|T|$  for  $|\tau|$  where  $\tau$  is the vocabulary of  $T$ .  $\mathbf{K} = \mathbf{K}_T$  is the class of atomic models of  $T$ . We write  $H = H(\mu)$  for the Hanf number for atomic models of all theories with  $|T| = \mu$ . By [She78]  $H$  equals  $\beth_{\delta(T)}$ , where  $\delta(T)$ , the well-ordering number of the class of models of a theory  $T$  omitting a family of types, is defined in VII.5 of [She78]. It is also shown there that if  $T$  is countable,  $H$  evaluates as  $\beth_{\omega_1}$  while for uncountable  $T$   $H = \beth_{(2^{|T|})^+}$ . Fix  $\mu_\alpha = \beth_\alpha(|T|)$ .

**Remark 1.2** In [She70], Shelah's definition of stability makes a stronger requirement; it implies *by definition* the existence of homogeneous models in certain cardinals. We do not make that assumption here so we are considering a larger class of theories.

**Definition 1.3** *1.  $\mathbf{K}$  is  $i$ -stable in  $\lambda$  (for  $i = \text{at}$  or  $\text{mod}$ ) if for every  $m < \omega$ , and  $M \in \mathbf{K}$  with  $|M| = \lambda$ ,  $|S_i^m(M)| = \lambda$ .*

2. *Stability classes.* For either  $i = \text{at}$  or  $\text{mod}$ ,

- (a)  $\mathbf{K}$  is  $i$ -stable if it is  $i$ -stable in some  $\lambda$ .
- (b)  $\mathbf{K}$  is  $i$ -superstable if it is  $i$ -stable in all  $\lambda \geq H$ .
- (c)  $\mathbf{K}$  is strictly  $i$ -stable if it is  $i$ -stable but not  $i$ -superstable.

For any  $M$ ,  $S_{\text{at}}(M)$  contains  $S_{\text{mod}}(M)$  so at-stability in  $\lambda$  implies mod-stability in  $\lambda$ . Thus for both notions  $\omega$ -stability implies stability in all powers by results of [She83a, She83b], expounded in [Bal09].

We prove Theorem A in Section 2 and Theorem B in Section 3. The proof of Theorem B uses an application of omitting types in Ehrenfeucht-Mostowski models generated by trees of the form  ${}^{<\omega}\lambda$ . This is by no means new technology but we weren't able to locate an explicit statement of the result so we include a proof in Section 4.

We acknowledge helpful discussions with Tapani Hyttinen, Ali Enayat and Lynn Scow.

## 2 Unstable $\mathbf{K}$

We first show that if there are cardinals  $\lambda_\alpha$  in which  $\mathbf{K}$  is 'sufficiently unstable', then  $\mathbf{K}$  is not stable in any cardinal.

**Theorem 2.1** *Suppose that for some positive integer  $m$  and for every  $\alpha < \delta(T)$ , there is an  $M_\alpha \in \mathbf{K}$  with  $|S_i^m(M_\alpha)| > |M_\alpha|^{\beth_\alpha(|T|)}$ . Then for every  $\lambda \geq |T|$ , there is an  $M$  with  $|S_i^m(M)| > |M| = \lambda$ .*

**Remark 2.2 (Proof Sketch)** Before the formal proof we outline the argument. We start with a sequence of models  $M_\alpha$  and many distinct types over each of them. By an argument which is completely uniform in  $\alpha$ , we construct triples  $\langle \mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i} \rangle$  for  $i < \mu_\alpha^+$  with the  $\mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i} \in M_\alpha$  and  $\mathbf{d}_{\alpha,i}$  in an elementary extension  $M'_\alpha$  of  $M_\alpha$  of the same cardinality and so that  $M_\alpha \mathbf{d}_{\alpha,i}$  is atomic and the distinctness of the types of the  $\mathbf{d}_{\alpha,i}$  is explicitly realized by formulas. Then we apply Morley's omitting types theorem to the  $M'_\alpha$  and extract from this sequence a countable sequence of order indiscernibles with desirable properties. Finally, this set of indiscernibles easily yields models of all cardinalities with the required properties.

**Remark 2.3** The idea of the proof can be seen by ignoring the  $\alpha$  and proving a slightly weaker result from one model of size  $\beth_{\delta(T)}$ .

**Notation 2.4**  $\lambda_\alpha = |M_\alpha|^{\beth_{\alpha+2}(|T|)}$ ;  $\mu_\alpha = \beth_\alpha(|T|)$ ;  $\kappa_\alpha = \beth_{\alpha+2}(|T|)$ .

**Lemma 2.5** *For some  $\tau_\Phi$  extending  $\tau$  with  $|\tau_\Phi| = |\tau|$ , there is  $\Phi$ , proper for linear orders, with fixed additional unary predicates  $P, P_1$  and binary  $R$  such that:*

1. For every linear ordering  $I$ ,  $N_I = EM_{\tau_\Phi}(I, \Phi) \models T$  and  $M_I = EM_\tau(I, \Phi) \upharpoonright P \in \mathbf{K}$ . Naturally  $J \subset I$  implies  $N_J \prec N_I$  and  $M_J \prec M_I$ .
2. The skeleton of  $N_I$  is  $\langle \mathbf{a}_i \widehat{\ } \mathbf{b}_i \widehat{\ } \mathbf{c}_i : i \in I \rangle$  and  $\text{lg}(\mathbf{c}_i) = m$ .

3. For some first order  $\phi$ :

$$N_I \models (\phi(\mathbf{c}_t, \mathbf{a}_s) \equiv \phi(\mathbf{c}_t, \mathbf{b}_s)) \text{ iff } s <_I t.$$

4.  $M_I \cup \mathbf{c}_i \subset N_I$  is atomic.

5. For  $S_{\text{mod}}(M)$ , we add the requirement that for each  $s \in I$ ,

$$M_{I,s} = N_I \upharpoonright \{d : N_I \models R(d, \mathbf{c}_s)\}$$

is an atomic elementary submodel of  $N_I$  containing  $M_I \mathbf{c}_s$ .

*Proof.* The proof of Lemma 2.5 requires a number of steps. Fix for each  $\alpha < \delta(T)$ ,  $M_\alpha \in \mathbf{K}$  such that  $|S_i^m(M_\alpha)| > \lambda_\alpha = |M_\alpha|^{\beth_{\alpha+2}(|T|)}$ . Fix  $p_{\alpha,i}$  for  $i < \lambda_\alpha^+$ , a list of distinct types in  $S_i^m(M_\alpha)$ . We work throughout in a monster model  $\mathbb{M}$  of  $T$ .

**Notation 2.6** In the following construction, we choose by induction triples  $\langle \mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i} \rangle$  for  $i < \mu_\alpha^+$ . We use the following notation for initial segments of the sequences.

1.  $D_{\alpha,i} = \{\mathbf{d}_{\alpha,j} : j < i\}$ .
2.  $X_{\alpha,i} = \{\mathbf{a}_{\alpha,j}, \mathbf{b}_{\alpha,j} : j < i\}$ .
3.  $q_{\alpha,i}$  is the type of  $d_{\alpha,i}$  over  $X_{\alpha,i}$ .

The following variant on splitting is crucial to carry out the construction. We call it ex-splitting (for external) because the elements which exemplify splitting are required to satisfy the same type over a set which is not in (so external to) the model.

**Definition 2.7** Let  $M$  be a model,  $X \subset M$  and  $D \subset \mathbb{M}$ . We say that  $p \in S_i^m(M)$  ex-splits over  $(D, X)$  if there exist  $\mathbf{a}, \mathbf{b} \in M, \mathbf{f} \in \mathbb{M}$  so that  $\mathbf{f}$  realizes  $p \upharpoonright X$ ,  $\mathbf{a} \equiv_D \mathbf{b}$  but  $(\mathbf{a}, \mathbf{f})$  and  $(\mathbf{b}, \mathbf{f})$  realize different types.

**Claim 2.8** The number of types in  $S_i^m(M_\alpha)$  that do not ex-split over a pair  $(D, X)$  with  $|X| = |D| = \beth_\alpha$  is  $\mu_{\alpha+2}$ .

*Proof.* Since it only strengthens the result while simplifying the exposition we let  $X = \emptyset$ . Let  $P_\alpha$  denote the collection of  $\text{tp}(\mathbf{e}/M_\alpha)$  with  $\text{lg}(\mathbf{e}) = m$  such that if  $\mathbf{a}, \mathbf{b} \in M_\alpha$  realize the same type over  $D$  then  $(\mathbf{a}, \mathbf{e})$  and  $(\mathbf{b}, \mathbf{e})$  realize the same type. Each type  $r$  in  $P_\alpha$  is determined by knowing for each  $i < |T|$  its restriction to one  $k$ -tuple from each equivalence class of the equivalence relation  $E_k$  on  $M_\alpha$  defined by  $\mathbf{a} E_k \mathbf{b}$  if  $\mathbf{a}$  and  $\mathbf{b}$  realize the same type over  $D$ . So, since  $|D| = \mu_\alpha$ , there are at most  $(2^{2^{\mu_\alpha}})^{|T|} = \mu_{\alpha+2}$  possible such  $r$ .  $\square_{2.8}$

As noted, for each  $M_\alpha$  we will be constructing by induction on  $i < \mu_\alpha^+$ , sets  $X_{\alpha,i}, D_{\alpha,i}$  of cardinality  $\mu_\alpha$ . We need to choose in advance a type  $p_\alpha$  which does not ex-split over any  $(X_{\alpha,i}, D_{\alpha,i})$  that arises. In order to do that we restrict the source of  $D_{\alpha,i}$ ; clearly  $X_{\alpha,i} \subset M_\alpha$ . That is, we will fix  $M'_\alpha$  with  $M_\alpha \prec M'_\alpha, |M'_\alpha| = \lambda_\alpha$  and

$M'_\alpha$  is  $\mu_\alpha^+$ -saturated and choose  $D_{\alpha,i} \subset M'_\alpha$ . (Note then that  $M'_\alpha$  is *not* in general atomic.)

Note that the number of types in  $S_i^m(M_\alpha)$  that do not ex-split over *any* pair  $(D, X)$  with  $|X| = |D| = \beth_\alpha$  is bounded by the number of such sets,  $|M'_\alpha|^{\mu_\alpha}$ , times the number of types in  $S_i^m(M_\alpha)$  that do not ex-split over a particular choice of  $(D, X)$ , which is  $\mu_{\alpha+2}$  by Claim 2.8. That is, the bound is  $|M'_\alpha|^{\mu_\alpha} \times \mu_{\alpha+2}$ . Since this number is less than  $\lambda_\alpha^+$ , we can fix a type  $p_\alpha \in S_i^M(M_\alpha)$  which does not ex-split over any of the relevant  $(D, X)$ .

**Definition 2.9** For each  $\alpha < \delta(T)$ , fix  $M'_\alpha$  with  $M_\alpha \prec M'_\alpha$ ,  $|M'_\alpha| = \lambda_\alpha$ , and  $M'_\alpha$  is  $\mu_\alpha^+$  saturated. Choose, by induction on  $i < \mu_\alpha^+$ , triples  $\mathbf{e}_{\alpha,i} = \langle \mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i} \rangle$  where

- a)  $\mathbf{d}_{\alpha,j} \in M'_\alpha$ .
- b)  $\mathbf{a}_{\alpha,i}, \mathbf{b}_{\alpha,i}$  are sequences of the same length from  $M_\alpha$  that realize the same type over  $D_{\alpha,i} = \{\mathbf{d}_{\alpha,j} : j < i\}$ .
- c) The types over the empty set of  $(\mathbf{a}_{\alpha,i}, \mathbf{d}_{\alpha,i})$  and  $(\mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i})$  differ.
- d)  $q_{\alpha,i} = p_\alpha \upharpoonright X_{\alpha,i} = \text{tp}(\mathbf{d}_{\alpha,i}/X_{\alpha,i})$  so if  $j < i$ ,  $q_{\alpha,j} \subseteq q_{\alpha,i}$ .
- e)  $M_\alpha \mathbf{d}_{\alpha,i}$  is an atomic set for each  $i$ . (In the mod-version  $N_{\alpha,i}$  is an atomic model containing  $M_\alpha \mathbf{d}_{\alpha,i}$ .)

**Construction 2.10** Choose  $\mathbf{d}_{\alpha,i}$  to realize  $p_\alpha \upharpoonright X_{\alpha,i}$ . By Claim 2.8, we can choose  $\mathbf{a}_{\alpha,i}$  and  $\mathbf{b}_{\alpha,i}$  to satisfy conditions a) and b). So we have

$$\text{tp}(\mathbf{d}_{\alpha,i}, \mathbf{a}_{\alpha,j}) = \text{tp}(\mathbf{d}_{\alpha,i}, \mathbf{b}_{\alpha,j}) \text{ if and only if } i < j. \quad (1)$$

We want this order condition for a single formula. For each  $i < \mu_\alpha^+$ , the types of  $(\mathbf{a}_{\alpha,i}, \mathbf{d}_{\alpha,i})$  and  $(\mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i})$  differ. That is,  $\phi_{\alpha,i}(\mathbf{a}_{\alpha,i}, \mathbf{d}_{\alpha,i})$  and  $\neg\phi_{\alpha,i}(\mathbf{b}_{\alpha,i}, \mathbf{d}_{\alpha,i})$  for some  $\phi_{\alpha,i}$ . By the pigeon-hole principal we may assume the  $\phi_{\alpha,i}$  is always the same  $\phi_\alpha$ . (Further, since  $|T|$  is not cofinal in  $\delta(T)$ , we can assume the  $\phi_\alpha$  is the same  $\phi$  for all  $\alpha$ .)

Suppose the construction is completed. We expand  $\tau$  to a language  $\tau_\Phi \supset \tau$  by adding predicates  $P, <, R$  and Skolem functions. We add Skolem axioms to  $T$  to get a theory  $T_1$  that admits quantifier elimination, requiring that these Skolem functions applied to elements of  $P$  give an element of  $P$  so that  $P$  will pick out an elementary submodel. (We make a similar requirement for  $R(x, \mathbf{y})$  in the mod-case.) Let  $M_\alpha^+$  be a model of  $T_1$  (submodel of  $M'_\alpha$ ) with cardinality  $\mu_\alpha^+$  containing  $M_\alpha$  and all the  $\mathbf{d}_{\alpha,i}$  ( $N_{\alpha,i}$  in the mod-case). Interpret  $P$  as the model  $M_\alpha$  and the relation  $<$  as the ordering on the triples  $\langle \mathbf{e}_{\alpha,i} : i < \mu_\alpha \rangle$  imposed by  $\phi_\alpha$ .

Assign the Skolem functions so that the  $\mathbf{e}_{\alpha,i}$  generate  $M'_\alpha$  and interpret  $R$  by

$$R = \{\widehat{e} \mathbf{d}_{\alpha,i} : e \in M_\alpha, i < \mu_\alpha^+\}.$$

(In the  $S_{\text{mod}}(M)$  case, interpret  $R$  as  $\{\widehat{e} \mathbf{d}_{\alpha,i} : i < \mu_\alpha^+, e \in N_{\alpha,i}\}$ .)

**Notation 2.11** Let  $\Gamma$  be the collection of types  $\mathcal{P}_n \cup \mathcal{Q}_n$ . Each non-principal  $n$ -type  $q$  over the empty set determines one element of  $\mathcal{P}_n$  and non-principal  $n + m$ -type  $q$  one of  $\mathcal{Q}_n$ :

1.  $\mathcal{P}_n = \{\bigwedge_{i < n} P(x_i)\} \cup \{q(\mathbf{x}) : q \text{ is a non-principal } n\text{-type}\}$
2.  $\mathcal{Q}_n = \{\bigwedge_{i < n} R(x_i, y)\} \cup \{q(\mathbf{x}, \mathbf{y}) : q \text{ is a non-principal } n + m\text{-type}\}$

Now apply Morley's omitting types theorem<sup>1</sup> to the  $\tau_\Phi$ -theory  $T_1$  and the collection of  $M_\alpha^+$  to get a countable sequence  $I$  of order indiscernibles and an extension  $\Phi$  of  $T_1$ , (the EM-template) such that  $\Phi$  is realized in each  $M_\alpha^+$  and such that for every linear order  $J$ ,  $EM_\tau(J, \Phi) \models T_1$  and omits  $\Gamma$ .

**Remark 2.12 (Morley's Method)** The next observation requires a little care in proving Morley's theorem rather than just quoting it. The  $M'_\alpha$  are generated by the  $\mathbf{e}_{\alpha, i}$  and we have interpreted  $<$  so that these are exactly the domain of  $<$ . So in proving the omitting types theorem, all witnesses for the consistency of the template  $\Phi(\mathbf{c})$  can be chosen from the domain of  $<$ . We use this fact below. It is this extra care that in the mind of the first author distinguishes "Morley's Method" from Morley's theorem. But this may be an idiosyncratic interpretation. The earliest mention of the phrase, I have found is in [She74] and that refers to applying the two cardinal theorem for cardinals far apart.

Note that any  $\tau_\Phi$  formula  $\phi(\mathbf{x})$  is in  $\Phi$  if it is true of every tuple  $\langle \mathbf{e}_{\alpha, i_1}, \dots, \mathbf{e}_{\alpha, i_n} \rangle$  with  $i_1 < i_2 < \dots < i_n$ . We describe a crucial such sentence.

Let  $\mathbf{x}^1 \mathbf{x}^2 \mathbf{x}^3$  be a triple of sequences with the first two having the same length as  $\lg(\mathbf{a}) = \lg(\mathbf{b})$  and the third has length  $m$ . Let  $\psi(\mathbf{x}, \mathbf{y})$  denote:

$$\phi(\mathbf{y}^3, \mathbf{x}^1) \equiv \phi(\mathbf{y}^3, \mathbf{x}^2).$$

Let  $\psi_1$  be the assertion that  $\phi$  defines a linear order on its domain; this directly translates precisely Lemma 2.5.3 and is true by the displayed statement 1. These structures clearly satisfy all the conditions of the requirements in Lemma 2.5 and we complete the proof.

□<sub>2.5</sub>

Proof of Theorem 2.1: To show instability in  $\lambda$ , let  $I$  be a dense linear ordering with cardinality  $\lambda$  and choose  $J \supset I$ , that realizes more than  $|I|$  cuts over  $I$ . Then  $EM_\tau(J, \Phi)$  realizes more than  $\lambda$  types in  $S_i^m(P(EM_\tau(I, \Phi)))$ . To see this, consider for any cut in  $I$  realized by an element  $j \in J$  the type:

$$\{\psi(\langle \mathbf{a}_i, \mathbf{b}_i, \mathbf{c}_i \rangle, \mathbf{x}, ) : i < j\} \cup \{\psi(\langle \mathbf{a}_i, \mathbf{b}_i, \mathbf{c}_i \rangle, \mathbf{x}, ) : i \geq j\}.$$

Then  $\langle \mathbf{a}_j, \mathbf{b}_j, \mathbf{c}_j \rangle$  realizes the type in  $EM_\tau(J, \Phi)$  and  $P(EM_\tau(J, \Phi))\mathbf{c}_j$  is an atomic set since  $\mathcal{Q}$  was omitted. For the mod-case, use the interpretation of  $R$  to define  $N_{\alpha, i}$ .

□<sub>2.1</sub>

<sup>1</sup>See Appendix A.3.1 of [Bal09] for a precisely tailored version. See [She78] or [Hod93], page 587 for a version with the role of the ordering more explicit. The latter two sources make the connection with the well-ordering number clear.

**Question 2.13** *Must an atomic class that is unstable in all  $\lambda$  have the order property?*

We say a class of atomic models has the *order property* if there is a sequence as in Lemma 2.5.3 but with the set of all the sequences being contained in atomic set. Condition 3) only requires each triple to be atomic. In particular we don't know the various  $c$ 's can appear together in any atomic model.

### 3 Strictly stable case

As the following examples show, it is easy to have superstable sentences of  $L_{\omega_1, \omega}$  that are not superstable for some values below  $H$ . The following theorem has two easily stated corollaries. If  $\mathbf{K}$  is not superstable then it is not stable in every  $\lambda$  with  $\lambda^\omega > \lambda$ . If  $\mathbf{K}$  is superstable then it is stable in some  $\lambda < H$ .

The results here are related to those in [GS86] but the combinatorics here is considerably simpler than in [GS86] for two related reasons. First, we construct tree indiscernibles indexed by  ${}^{<\omega}\lambda$  while they are concerned with  ${}^{\leq\omega}\lambda$ ; the limit node is much more difficult to handle. Second, they are constructing many non-isomorphic models, we only construct many different types. To obtain these stronger results, they assume the existence of large cardinals while this paper is in ZFC.

**Example 3.1** For  $\alpha < \omega_1$ , let  $\phi_\alpha$  be Morley's sentence that has a model in  $\beth_\alpha$  but no larger model. It is easy to see that the sentences are not stable in the cardinalities where they have models. Let  $\psi$  be the Scott sentence of an infinite set with only equality. Now let  $\psi_\alpha$  assert that either a structure has a nontrivial relation and obeys  $\phi_\alpha$  or just  $\psi$ . Then  $\phi_\alpha$  is  $\beth_\alpha$ -unstable but stable (indeed categorical in all cardinals beyond  $\beth_{\omega_1}$ ).

If one adds even joint embedding such trivial examples are no longer apparent.

We retain the value of  $\mu_\alpha$  from the first section but  $\lambda_\alpha$  is redefined in the hypothesis of the next theorem.

**Theorem 3.2** *Suppose that for every  $\alpha < \delta(T)$ , there is  $M^\alpha \in \mathbf{K}$  such that  $\lambda_\alpha = |M^\alpha| \geq \mu_\alpha$  and  $S_i^m(M^\alpha) > \lambda_\alpha$ . Then for any  $\mu$  with  $\mu^{\aleph_0} > \mu$ ,  $\mathbf{K}$  is not stable in  $\mu$ .*

*Proof.* Fix for each  $\alpha < \delta(T)$ ,  $M^\alpha \in \mathbf{K}$  such that  $|S_i^m(M^\alpha)| > \lambda_\alpha$ . Fix  $p_{\alpha, i}$  for  $i < \lambda_\alpha^+$ , a list of distinct types in  $S_i^m(M^\alpha)$ . We work throughout in a monster model  $\mathbb{M}$  of  $T$ .

To prepare for the application of an appropriate version of Morley's omitting types theorem we construct a sequence of models and certain types. For this, we construct trees of types that arise from failure of stability. The combinatorics slightly extends the classical arguments and avoids compactness. Note that this stage of the construction takes place in the original language. We will apply the following general result uniformly to each  $M^\alpha$ .

**Fact 3.3** *Suppose  $|M| \geq \mu_{\alpha+1}$  and  $\mathcal{P}$  is a collection of  $> \lambda_\alpha = |M|$  members of  $S_i^m(M)$ . Then there exists a sequence  $\langle \mathbf{b}_j : j < \mu_\alpha \rangle$  with each  $\mathbf{b}_j \in M$  and a formula  $\phi(\mathbf{x}, \mathbf{y}) = \phi_{\mathcal{P}}$  such that for each  $j < \mu_\alpha$ ,*

$$|\{p \in \mathcal{P} : i < j \rightarrow \phi(\mathbf{x}, \mathbf{b}_i) \in p \text{ but } \neg\phi(\mathbf{x}, \mathbf{b}_j) \in p\}| > \lambda_\alpha. \quad (2)$$

Proof. We consider many possibilities for  $\phi$  and prove one works. We choose  $\{\phi_\eta : \eta \in T_i\}$  by induction on  $i < \mu_\alpha$  where each  $T_i$  is a subset of  ${}^i 2$  and each  $\mathbf{b}_\eta \in M^\alpha$  so that

1.  $j < i$  and  $\eta \in T_i$  implies  $\eta \upharpoonright j \in T_j$ .
2. if  $\eta \in T_i$  then  $p_\eta = \{\phi_{\eta \upharpoonright j}(\mathbf{x}, \mathbf{b}_{\eta \upharpoonright j})^{\eta(j)} : j < i\}$  is included in  $> \lambda_\alpha$  members of  $\mathcal{P}$ .
3. For limit  $i$ ,

$$T_i = \{\eta \in {}^i 2 : (\forall j < i) \eta \upharpoonright j \in T_j \text{ and } p_\eta \text{ is included in } > \lambda_\alpha \text{ members of } \mathcal{P}\}$$

4. if  $i = j + 1$  then  $T_i = \{\eta \widehat{0}, \eta \widehat{1} : \eta \in T_j\}$ .

For the successor step in the induction recall the following crucial observation of Morley. Suppose there are more than  $|M|$  types over  $M$  extending a partial type  $p$ . Then there exists a formula  $\phi(\mathbf{x}, \mathbf{a})$  with  $\mathbf{a} \in M$  such that both  $p \cup \{\phi(\mathbf{x}, \mathbf{a})\}$  and  $p \cup \{\neg\phi(\mathbf{x}, \mathbf{a})\}$  have more than  $|M|$  extensions to complete types over  $M$ . (We are extending Morley's analysis to types in  $S_i^m(M)$  but the argument is just counting; otherwise there is a unique type obtained by always choosing the big side.)

The interesting point in the induction is the limit stage. We cannot guarantee that individual paths survive. But at each stage in the induction, we have defined types over a set of cardinality  $\mu_\alpha$ . So there are at most  $\mu_{\alpha+1}$  types over  $\{\mathbf{b}_\eta : \text{lg}(\eta) < \delta\}$ . So one of the paths must have more than  $\lambda_\alpha$  extensions to  $S_i^m(M)$ .

So  $T_{\mu_\alpha} \neq \emptyset$ . Choose  $\eta \in T_{\mu_\alpha}$ . Let  $\phi'_j(\mathbf{x}, \mathbf{b}_j) = \phi_{\eta \upharpoonright j}(\mathbf{x}, \mathbf{b}_{\eta \upharpoonright j})^{\eta(j)}$  for  $j < \mu_\alpha$ . But since the path has length  $\mu_\alpha = \beth_\alpha(T)$ , by the pigeonhole principle we may assume there is a single formula  $\phi$ . This completes the construction of the  $\phi$  and the  $\mathbf{b}_j$ .  $\square_{3.3}$

Now we apply this fact to construct from the original  $M^\alpha$  given in the hypothesis of Theorem 3.2 a sequence of models  $\hat{M}^\alpha$  and associated sequences  $\mathbf{b}_{\alpha,\rho}$  and  $\mathbf{c}_{\alpha,\rho}$  for  $\rho \in {}^{<\omega} \mu_\alpha$ .

**Definition 3.4** Let  $\hat{M}^\alpha$  be a  $\mu_\alpha^+$  saturated elementary extension of  $M^\alpha$ . We construct for each  $\alpha$  by induction on  $n < \omega$ , submodels  $M_n^\alpha$  of  $M^\alpha$  and types  $\{q_\nu^\alpha : \nu \in {}^{<\omega} \mu_\alpha\}$  with  $q_\nu^\alpha \in S_i^m(M_{\text{lg}(\nu)}^\alpha)$  and realizations  $\mathbf{c}_{\alpha,\nu} \in \hat{M}^\alpha$  of  $q_\nu^\alpha$  satisfying the following conditions.

1.  $\langle M_n^\alpha : n < \omega \rangle$  is an increasing chain of submodels of  $M^\alpha$ , each with cardinality  $\mu_\alpha$ .
2. If  $k \leq n$  and  $\nu \in {}^k \mu_\alpha$ , then  $q_\nu^\alpha \in S_i^m(M_k^\alpha)$ .
3. Each  $q_\nu^\alpha \in S_i^m(M_n^\alpha)$  has  $> \lambda_\alpha$  extensions to  $S_i^m(M^\alpha)$
4. Suppose  $k < r \leq n$ ,  $\nu \in {}^k \mu_\alpha$ ,  $\rho \in {}^r \mu_\alpha$  and  $\rho$  extends  $\nu$ :

$$q_\nu^\alpha \subseteq q_\rho^\alpha.$$

5. If  $\nu \in {}^k \lambda_\alpha$ ,  $k < n$ ,  $i \neq j$ , then

$$q_{\nu \widehat{i}}^\alpha \neq q_{\nu \widehat{j}}^\alpha.$$

They are distinguished by the  $\mathbf{b}_{\alpha, \rho}$ , as specified in statement 3 below.

6.  $\mathbf{c}_{\alpha, \nu} \in \hat{M}_\alpha$  realizes  $q_\nu^\alpha$ . (In the mod-case,  $N_{\alpha, \rho}$  is the universe of an atomic model containing  $M\mathbf{c}_{\alpha, \rho}$ .)

**Construction 3.5** We use Fact 3.3 to construct objects meeting this definition. Let the subscript  $x$  denote at or mod. By induction, for each  $\rho \in {}^n \mu_\alpha$  the type  $q_\rho^\alpha \in S_{xt}^m(M_n^\alpha)$  has  $> \lambda_\alpha$  extensions to  $S_x^m(M^\alpha)$ . Let  $\mathcal{P}_\rho = \{r \in S_x(M_\alpha) : q_\rho^\alpha \subseteq r\}$  so  $|\mathcal{P}_\rho| > \lambda_\alpha$ . By Fact 3.3, we find  $\langle \mathbf{b}_{\alpha, \widehat{\rho}j} : j < \mu_\alpha \rangle$  and  $\phi_\rho$  satisfying displayed statement 2.

Let  $M_{n+1}^\alpha$  be a submodel of  $M^\alpha$  with  $M_n^\alpha \cup \{\mathbf{b}_{\alpha, \rho} : \rho \in {}^{n+1}(\mu_\alpha)\} \subseteq M_{n+1}^\alpha$  and with cardinality  $\mu_\alpha$ .  $M_{n+1}^\alpha \subset M_\alpha$  so is an atomic model and each  $q_\rho^\alpha$  extends to an atomic type over  $M^\alpha$ .

For  $\rho \in {}^n(\mu_\alpha)$  and  $i < \mu_\alpha$  first define

$$p'_{\rho \widehat{i}} = q_\rho^\alpha \cup \{\phi_\rho(x, \mathbf{b}_{\alpha, \widehat{\rho}j}) : j < i\} \cup \{\neg \phi_\rho(x, \mathbf{b}_{\alpha, \widehat{\rho}i})\}.$$

Since  $\lambda_\alpha < |\{r \in S_x(M^\alpha) : p'_\rho \subseteq r\}|$ , we can find  $p_{\rho \widehat{i}}^\alpha \in S_x^m(M_n^\alpha)$  extending  $p'_{\rho \widehat{i}}$  such that  $\mathcal{P}_{\rho \widehat{i}} = \{r \in S_x(M^\alpha) : p_{\rho \widehat{i}}^\alpha \subseteq r\}$  has cardinality  $> \lambda_\alpha$ . Note that

$$p_{\rho \widehat{i}}^\alpha \supseteq q_\rho^\alpha \cup \{\phi_\rho(x, \mathbf{b}_{\alpha, \widehat{\rho}j}) : j < i\} \cup \{\neg \phi_\rho(x, \mathbf{b}_{\alpha, \widehat{\rho}i})\}.$$

This completes the  $n + 1$ st stage of the construction. So we can construct the  $M_n^\alpha$  and  $\{q_{\nu, i} : \nu \in {}^{<\omega} \mu_\alpha\}$ ,  $\hat{M}^\alpha$  and by  $\mu_\alpha^+$ -saturation choose  $\mathbf{c}_{\alpha, \rho} \in \hat{M}^\alpha$ . In the mod-case choose an atomic model  $N_{\alpha, \rho}$  with  $M^\alpha \mathbf{c}_{\alpha, \rho} \subset N_{\alpha, \rho} \prec \hat{M}^\alpha$ . Note

$$\{\phi_\rho(\mathbf{c}_{\alpha, \widehat{\rho}i}, \mathbf{b}_{\alpha, \widehat{\rho}j}) : j < i\} \cup \{\neg \phi_\rho(\mathbf{c}_{\alpha, \widehat{\rho}i}, \mathbf{b}_{\alpha, \widehat{\rho}i})\}. \quad (3)$$

We expand  $\tau$  to a language  $\tau_\Phi \supset \tau$  in two stages. Form  $\tau'$  by adding predicates  $P, P_n, <, <^*, R$  and Skolem functions. We add Skolem axioms to  $T$  to get a theory  $T'$  that admits quantifier elimination, requiring that these Skolem functions applied to elements of  $P$  give an element of  $P$  so that  $P$  will pick out an elementary submodel.

Let  $M_\alpha^+$  be a model of  $T$  (submodel of  $\hat{M}^\alpha$ ) with cardinality  $\mu_\alpha$  containing  $M_n^\alpha$  for  $n < \omega$  and all the  $\mathbf{c}_{\alpha, \rho}$ . Assign the  $\tau'$ -Skolem functions so that  $P(\hat{M}^\alpha) = M^\alpha = \bigcup_{n < \omega} M_n^\alpha$  is generated by the  $\mathbf{b}_{\alpha, \rho}$  for  $\rho \in {}^{<\omega} \mu_\alpha$ . Let  $X_\alpha$  be the tree with domain  $\langle \mathbf{b}_{\alpha, \rho} : \rho \in {}^{<\omega}(\mu_\alpha) \rangle$  and the following relations. Interpret  $<$  as the partial order on the  $\langle \mathbf{b}_{\alpha, \rho} : \rho \in {}^{<\omega}(\mu_\alpha) \rangle$  given by inclusion on the indices. Let  $<^*$  be a linear order of the  $\langle \mathbf{b}_{\alpha, \rho} : \rho \in {}^{<\omega}(\mu_\alpha) \rangle$  given by lexicographic order on the indices. Interpret  $R$  as

$$\{e \widehat{\mathbf{c}}_{\alpha, \rho} : \rho \in {}^{<n}(\mu_\alpha), e \in \bigcup_{n < \omega} M_n^\alpha\}.$$

Form  $\tau_\Phi$  by adding function symbols  $F_n$ . Define  $F_n(\mathbf{b}_{\alpha, \rho}) = \mathbf{c}_{\alpha, \rho}$ . Now let  $T_1$  be the collection of all  $L(\tau_\Phi)$ -sentences that are true in each  $\hat{M}_\alpha$ .

In the  $S_{\text{mod}}(M)$  case, we must do a bit more. Interpret  $R$  as  $\{\widehat{\mathbf{e}}_{\mathbf{c}_{\alpha,\rho}} : \rho \in <^n(\mu_\alpha), \text{ and } \mathbf{e} \in N_{\alpha,\rho}\}$ . Define the  $\tau'$ -Skolem functions so that the Skolem closure of  $M\mathbf{c}_{\alpha,\rho}$  is  $N_{\alpha,\rho}$ . This implies that if  $R(\mathbf{e}, \mathbf{c}_{\alpha,\rho})$  holds then  $\mathbf{e}$  is a sequence given by  $\tau'$ -Skolem functions with arguments a finite number of members of  $P(M_\alpha^+)$  and  $\mathbf{c}_{\alpha,\rho}$ .

Observe:

**Claim 3.6** *For any finite linearly ordered initial  $<$ -segment of the tree with length  $n + 1$ , enumerated by  $\mathbf{x}_0, \dots, \mathbf{x}_n$ , (so  $P_i(\mathbf{x}_i)$ ):*

1.  $\bigwedge_{i \leq n} P_i(\mathbf{z}) \wedge \mathbf{z} <^* \mathbf{x}_i \wedge \phi_i(F_n(x_n), \mathbf{z})$
2.  $\bigwedge_{i \leq n} \neg \phi_i(F_n(x_n), \mathbf{x}_i)$ .

The universal quantification of each such sentence is true in each  $\hat{M}_\alpha$  and so is in  $T_1$ .

As in Notation 2.11 let  $\Gamma$  be the collection of types:

1.  $\mathcal{P}_n = \{\bigwedge_{i < n} P(x_i)\} \cup \{q(\mathbf{x}) : q \text{ is a non-principal } n\text{-type}\}$
2.  $\mathcal{Q}_n = \{\bigwedge_{i < n} R(x_i, \mathbf{y})\} \cup \{q(\mathbf{x}, \mathbf{y}) : q \text{ is a non-principal } n + m\text{-type}\}$

Now apply the omitting types theorem (as stated in Section 4) to the  $\tau_\Phi$ -theory  $T_1$  and the collection of  $M_\alpha^+$  to get a countable set of tree-indiscernibles in order type  $<^\omega \omega$  and an extension  $\Phi$  of  $T_1$ , (the EM-template) such that for every tree of  $J$  of order  $<^\omega \lambda$ ,  $EM_\tau(J, \Phi) \models T_1$  and omits  $\Gamma$ .

Finally we must show there are many types; we separate the cases.

**Claim 3.7** *If  $\lambda^\omega > \lambda$  then there is an  $I$  with  $|I| = \lambda$  such that  $S_{\text{at}}^m(M_I) > \lambda$ , where  $M_I = EM(I, \Phi) \upharpoonright P$ .*

Proof. Note that by 3 and Claim 3.6 we have:

1. If  $\rho, \widehat{\rho}i \in I$ ,  $\text{tp}(F_n(\rho)/P_n(M)) \subseteq \text{tp}(F_{n+1}(\widehat{\rho}i)/P_{n+1}(M))$ .
2. If  $\rho \in I$  and  $i \neq j$ ,

$$\text{tp}(F_{n+1}(\widehat{\rho}j)/P_{n+1}(M)) \neq \text{tp}(F_{n+1}(\widehat{\rho}i)/P_{n+1}(M)).$$

Now in any  $M_I = EM(I, \Phi)$  for any  $\rho \in J$  define  $p_\rho \in S_{\text{at}}^m(P_N(M_I)) = \text{tp}(F_n(\rho), P_n(M))$ . Now letting  $p_\eta \in S_{\text{at}}^m(P(M_I))$  be  $\bigcup_{i < \omega} p_{\eta \upharpoonright n}$ , we find  $\lambda^\omega$  members of  $S_{\text{at}}^m(P(M_I))$ . The definition of  $S_{\text{at}}^m$  guarantees the union is in  $S_{\text{at}}^m$ .  $\square_{3.7}$

Now we extend this result to mod.

**Claim 3.8** *If  $\lambda^\omega > \lambda$  then there is an  $I$  with  $|I| = \lambda$  such that  $S_{\text{mod}}^m(M_I) > \lambda$ , where  $M_I = EM(I, \Phi) \upharpoonright P$ .*

Proof. We need to construct an atomic model  $N_\eta$  containing  $M_I \mathbf{c}_\eta$  (from the proof of Claim 3.7). The natural choice is the  $\tau'$ -Skolem closure of  $M_I \mathbf{c}_\eta$ . The reason the reduct of this structure to  $\tau$  is atomic is that any finite sequence is of the form  $\mathbf{a}, \mathbf{b}$  where the  $\mathbf{a}$  come from  $P_n(M_I)$  (for a fixed  $n$ ) and each of the  $\mathbf{b}$  has the form  $G(\mathbf{a}, \mathbf{c}_\eta)$  where  $G$  is a  $\tau'$ -Skolem function. But then the  $\tau$  type of  $\mathbf{a}\mathbf{b}$  is the same as the  $\tau$ -type of a sequence  $\mathbf{a}'\mathbf{b}'$  where  $\mathbf{a}' \in P_n(\hat{M}^\alpha)$  and each  $\mathbf{b}' \in N_{\alpha, \rho}$  is of the form  $G(\mathbf{a}', \mathbf{c}_\eta \upharpoonright n)$ .  $\square_{3.8}$

## 4 Tree Indiscernibility

The main result of this section is the existence of tree indiscernibles as needed in the previous section. But we take the occasion to discuss the role of various types of index sets for indiscernible collections and to make explicit role of expanding the vocabulary when finding indiscernibles in various contexts.

The theorem reported here is implicit in the literature (e.g. [She78, GS86]) but we could not find an explicit statement. Theorem VII.3.6 of [She78] finds an indiscernible tree in the first order case on  ${}^{<\omega}\omega$  but we want to omit types as well. The basic plan of the proof dates to Morley [Mor65]. We indicate the modifications needed for the more complicated combinatorics to build models to omit types that are over indiscernible trees instead of over linear orders.

Many variants of tree indiscernibles are used in various parts of model theory; we sketch the contexts to point out where the current version lies.

	linear order	${}^{<\omega}2$	${}^{<\omega}\lambda$	$\leq^\omega \lambda$
In $\tau$	1	2	3	4
In $\tau_\Phi$	5	6	7	8

In this chart the first column labels the row. In the first row, the ordering is explicitly defined in the base language; in the second row it is not. Thus the first row describes examples where the (tree)-ordering is definable in the original vocabulary.

Indiscernibles may be ordered by linear orders, or trees of the form  ${}^{<\omega}2$ ,  ${}^{<\omega}\lambda$  or even  $\leq^\omega 2$ ,  $\leq^\omega \lambda$ . We may want to find the ordering in the basic language (to witness instability at some level) or not (to avoid introducing instability). In some cases the order is explicit in the expanded language; in others it is not. Ehrenfeucht and Mostowski (5) did not introduce the order to the base language (so second row) and built the tree over a linear order (first column). In his construction of many models of unstable theories [She71, She78], Shelah (1) is in the first column, first row. To investigate stable but not superstable theories, we (3) want the first row, third column. The exposition here differs from [She78], where the number of models of an unsuperstable theory is computed, because in working with  $L_{\omega_1, \omega}$ , we must omit types. In VII.3.6 of [She78], Erdos-Rado is applied to show the existence of a ‘uniform’  $\beta$ -tree implies the existence of a tree of indiscernibles indexed by  ${}^{<\omega}\omega$ . The use (2) of trees indexed by  $2^{\leq \omega}$  to construct many models in  $\aleph_1$  if a countable theory is not  $\omega$ -stable appears in [She78]. (The tree is found in VI.3.7; it is used to construct many models in VIII.1.2.) An exposition of this result and some extensions to uncountable languages occur in [Bal89]. There are

further applications to two-cardinal models [She75, She76] and to Peano arithmetic (6) [MP84]. Tree indiscernibles on  ${}^{<\omega}2$  rely on Halpern-Lauchli etc; tree indiscernibles on  ${}^{<\omega}\omega$  rely on Erdos-Rado. The construction of many models from infinitary order properties in [GS86] (4) requires large cardinal axioms for the combinatorics.

We see three steps in this kind of construction. The references in parentheses are to the application of this method to the proof in Section 3.

1. Model theoretic construction of specific syntactic-combinatoric configurations on models. (Construction 3.5.)
2. Application of Erdos-Rado or Halpern-Lauchli and compactness to extract a countable family of indiscernibles. (Theorem 4.7.)
3. Application of Ehrenfeucht-Mostowski models to obtain models of arbitrary cardinality. (Claim 3.7.) This is sometimes called ‘stretching’.

We first establish some background notation. The exact language of the partial order is significant; the language here is considerably more expressive than that in [She75].

**Notation 4.1** 1. A tree  $\mathbf{T}$  is a subset of  ${}^{\leq\omega}\lambda$  that is closed under initial segment.

2.  $\text{atp}$  means atomic (quantifier-free) type.
3. The vocabulary  $\tau^*$  will denote the language of trees we use. It contains the partial order on the tree,  $<$ , the lexicographic order on the tree  $<^*$ , and the levels  $P_n$ .  $\tau_n^*$  omits the  $P_i$  with  $i > n$ .
4. When elements  $\mathbf{a}_\eta$  and  $\mathbf{a}_\tau$  in a structure  $M$  are indexed by  $\eta, \tau \in \mathbf{T}$  that realize the same quantifier free  $\tau^*$ -type in the tree then  $\mathbf{a}_\tau$  and  $\mathbf{a}_\eta$  have the same length.
5. If  $\nu$  is an  $n$ -element sequence from  $\mathbf{T}$ ,  $\mathbf{a}_\nu$  denotes  $\langle \mathbf{a}_{\nu(0)}, \dots, \mathbf{a}_{\nu(n-1)} \rangle$ .

**Definition 4.2** For any vocabulary  $\tau$ , let  $M$  be a  $\tau$ -structure and  $\Sigma$  a set of  $\tau$ -formulas.

If  $\text{atp}_{\tau^*}(\eta/\emptyset) = \text{atp}_{\tau^*}(\nu/\emptyset)$  implies  $\text{tp}_\Sigma(\mathbf{a}_\tau/\emptyset) = \text{tp}_\Sigma(\mathbf{a}_\eta/\emptyset)$  in  $M$  then we call  $\langle \mathbf{a}_\eta : \eta \in \mathbf{T} \rangle \subset M$  a set of  $\Sigma$ -tree indiscernibles:

We just say tree indiscernibles if  $\Sigma$  contains all formulas in  $L(\tau)$ .

We rely on a combinatorial lemma that follows from Erdos-Rado. The result is proved as Theorem 2.6 in the appendix to [She78]. A stronger result (the bound on  $k(m, n)$  is smaller) with a shorter proof appears in the appendix of [GS86].

**Lemma 4.3 ([She78])** For every  $n, m < \omega$ , there is a  $k(n, m) < \omega$  such that if  $\lambda = \beth_k(\chi)^+$  the following is true. For any function  $f: [{}^{\leq n}\lambda]^m \rightarrow \chi$ , there exists a  $\mathbf{T} \subseteq {}^{\leq n}\lambda$  such that

1. Each  $\eta \in \mathbf{T}$  has  $\chi^+$  immediate successors in  $\mathbf{T}$ .
2. If  $\nu$  and  $\tau$  are  $m$ -tuples from  $\mathbf{T}$  with  $\text{atp}_{\tau^*}(\eta/\emptyset) = \text{atp}_{\tau^*}(\nu/\emptyset)$ , then  $f(\tau) = f(\eta)$ .

We now prove the theorem on the existence of tree-indiscernibles. In order to be clear about the definability of the tree in the original language we extend Notation 4.1 and are quite pedantic about the vocabularies involved.

**Notation 4.4** 1.  $\tau_\Phi$  includes both  $\tau$  and  $\tau^*$  and includes Skolem functions for  $\tau_\Phi$ , where the Skolem axioms and relations with crucial  $\tau$ -formulas are axiomatized in a  $\tau_\Phi$ -theory  $T_1$ .

2. The set of constants  $C$  which guarantee the consistency of the order are added to  $\tau_\Phi$ .

3.  $\Sigma_i$  denotes the set of  $\phi \in \tau_\Phi - \{P_j : j > i\}$  with at most  $i$  free variables.

Tree-indiscernibles are a special case of generalized indiscernibility as defined in VII.2 of [She78]. Indiscernibles indexed by other types of structure appear for example in [LS03, DS04, Sco]. The following notion, based on one introduced by Scow[Sco] in a slightly different context is helpful for stating the results here. The point is that although the type of infinite collection of indiscernibles may not be realized in any of the input models, each finite subtype is. Thus properties of finite character (such as realizing a finite type) follow immediately if the indiscernibles have the modeling property.

**Definition 4.5** A collection of  $\Sigma$ -tree-indiscernibles  $B = \{b_\eta : \eta \in \mathbf{T}\}$  has the modeling property if for some  $(M_\alpha, X_\alpha)$  (where  $M_\alpha \supset X_\alpha = \{a_\eta : \eta \in \mathbf{T}_\alpha\}$ , and  $\mathbf{T}_\alpha \approx \mathbf{T}$  (isomorphic) for  $\alpha < H$ ) if for every finite sequence  $\nu$  from  $\mathbf{T}$  and every sequence  $\mathbf{b}_\nu$  from  $B$  and each  $\alpha$  there is a sequence  $\mathbf{a}_{\nu'}$  in  $X_\alpha$  with  $\nu'$  having the same  $\tau^*$  type as  $\nu$  and such that  $\mathbf{a}_{\nu'}$  and  $\mathbf{b}_\nu$  have the same  $\Sigma$ -type.

Note that in the argument below when the  $X_\alpha$  are refined using Lemma 4.3 a tuple  $\mathbf{a}_{\nu'} \in X_{\alpha,n}^i$  was originally named  $\mathbf{a}_{\nu'} \in X_{\alpha+m^*,n}^0$  (where  $m^* < \omega$  can be easily computed). But,  $\nu$  and  $\nu'$  realize the same  $\tau^*$ -type.

**Remark 4.6** There are at least four approaches to the proof of Morley's omitting types theorem that differ subtly. In [CK73, Mar02]<sup>2</sup> the language is countable and there are separate steps to guarantee indiscernibility and omission of the types (meeting indiscernibility type omission requirements in turn for each formula and for each type). In the argument here, we use the Skolemization of the models  $M_\alpha$  to deduce the omission of types from the indiscernibility. This argument strategy is forced because in dealing with uncountable languages, working with one formula at each step makes the induction too long. We replace this by working with all formulas with  $n$  free variables at step  $n$ . The arguments in [She78, GL02, GS86] employ nonstandard-models of set theory. Finally, the arguments in [Hod87, Kei71], work directly in infinitary logic using Hintikka sets or consistency properties. The arguments of [She78, GS86, Hod87] make the connection with well-ordering numbers explicit.

Recall that  $\mu_\alpha = \beth_\alpha(|T|)$ . Writing  $\mu_\alpha$  rather than  $\beth_\alpha$  and considering  $M_\alpha$  for  $\alpha < \delta(T) = (2^{|T|})^+$  is part of the price for dealing with uncountable  $T$ .

<sup>2</sup>Compare comments on the proof in [CK73]. The stated result is the existence of large models omitting types without mentioning indiscernibility.

Note that when applying this theorem in Section 3, the  $M_\alpha$  here are the  $M_\alpha^+$  (as Skolemized) there.

**Theorem 4.7** *Let  $T_1$  be a theory with Skolem functions in a vocabulary  $\tau_\Phi$ . Suppose for  $\alpha < \delta(T)$ , there exists a model  $M_\alpha$  of  $T_1$  with  $|M_\alpha| \geq \mu_\alpha$  such that  $M_\alpha$  omits a family  $\Gamma$  of  $\tau$ -types.  $\tau_\Phi$  contains the vocabulary  $\tau^*$  and  $X_\alpha$  is a set of elements in  $M_\alpha$  that form a tree of type  ${}^{<\omega}\mu_\alpha$  in  $M_\alpha$  defined by the interpretations of  $<, <^*, P_n$ . In particular  $X_{\alpha,n}$  is the restriction of  $X_\alpha$  to  $P_n$ ; it has order type  $\leq^n \mu_\alpha$ .*

*Then, there is a countable set of tree-indiscernibles  $C = \langle c_\tau : \tau \in I \rangle$  with  $I$  of order type  ${}^{<\omega}\omega$  such that  $C$  has the modeling property with respect to  $(M_\alpha, X_\alpha)$  and an extension  $\Phi$  of  $T$  such that for every tree  $J$  of the form  ${}^{<\omega}\lambda$ ,  $EM_\tau(J, \Phi) \models T$ , witnesses the universal  $\tau_\Phi$ -sentences that are true on all  $X_\alpha$ , and omits  $\Gamma$ .*

*Proof.* After expanding the language  $\tau_\Phi$  with new constants  $\langle c_\rho : \rho \in {}^{<\omega}\omega \rangle$ , we need to demonstrate the consistency of the following families of sentences.

1.  $c_\rho \neq c_\eta$  if  $\rho \neq \eta$ .
2. For each  $\tau_\Phi$ -formula  $\phi(\mathbf{v})$ , for each quantifier-free  $\tau^*$ -type  $r$ . If  $\eta, \nu$  both realize  $r$ ,

$$\phi(\mathbf{c}_\nu) \equiv \phi(\mathbf{c}_\eta).$$

3. For each  $\ell$ -type  $p \in \Gamma$ , for each sequence of  $\ell$   $\tau_\Phi$ -terms  $t_i(\mathbf{u})$  with  $\text{lg}(\mathbf{u}) = m$  ( $\mathbf{t}(\mathbf{u}) = \langle t_0(\mathbf{u}), \dots, t_{\ell-1}(\mathbf{u}) \rangle$ ) and each quantifier-free  $\tau^*$ - $m$ -type  $r$ , there is a  $\phi_p(v_0, \dots, v_{\ell-1})$ , such that if  $\nu$  realizes  $r$

$$\neg \phi_p(\mathbf{t}(\mathbf{c}_\nu)).$$

4. If  $\psi$  is the universal quantification of a  $\tau_\Phi$ -formula  $\chi(\mathbf{x}_1, \dots, \mathbf{x}_n)$  that is true in all  $X_\alpha$  (i.e. on the substructure of the  $\tau_\Phi$  expansion of  $M_\alpha$  with universe  $X_\alpha$ ) then  $\chi(\mathbf{c}_1, \dots, \mathbf{c}_n) \in \Phi$ .

Let  $\mathbf{T} \subseteq {}^{<\omega}\lambda$  and  $\mathbf{T}_n = \mathbf{T} \cap \leq^n \lambda$ . We begin with pairs  $(M_\alpha, X_{\alpha,n}^0)$  for  $n < \omega$ , a model  $M_\alpha$ , and a subset  $X_{\alpha,n}^0 = \{\mathbf{a}_\tau : \tau \in \mathbf{T}_{\alpha,n}\}$  which contains a sufficiently large tree as in the hypothesis of the theorem. Here,  $\mathbf{T}_\alpha \subseteq {}^{<\omega}\mu_\alpha$  and  $\mathbf{T}_{\alpha,n} = \mathbf{T} \cap \leq^n \mu_\alpha$ .

We construct by induction for  $i < \omega$  and for each  $n$  a pair  $(M_\alpha^i, X_{\alpha,n}^i)$  with  $X_{\alpha,n}^i = \{\mathbf{a}_\tau : \tau \in \mathbf{T}_{\alpha,n}^i\} \subset \bigcup_{j \leq n} P_j(M_\alpha^i)$ . And we construct the diagram  $\Phi$ , checking its finite consistency. Let  $\Phi_0$  include all  $\tau_\Phi$  sentences true in all  $X_{\alpha,n}^0$  and the assertion that the  $c_\rho$  are distinct.

At stage  $i$ , we apply the next result, Claim 4.8.

**Claim 4.8** *Let  $S_n$  be the collection of  $\tau_\Phi$ - $n$ -types over the empty set which are realized in  $\bigcup_{i \leq n} P_n(M_\alpha)$  (i.e. the  $\Sigma_n$ -types). The sequence  $(M_\alpha^i, X_{\alpha,n}^i)$  has the property that for each  $\alpha$ :*

*If  $\eta, \nu \in \mathbf{T}_{\alpha,n}^i$  both realize the same quantifier-free  $\tau^*$ -type  $r$ , and  $n \geq i$  then for each  $\phi \in \Sigma_i$*

$$\phi(\mathbf{c}_\eta) \equiv \phi(\mathbf{c}_\nu). \tag{4}$$

*Moreover,  $(X_{\alpha,n}^i, <, <^*) \approx \leq^n \mu_\alpha$ .*

Proof. Consider  $(M_{\alpha+k}^i, X_{\alpha+k,i}^i)$  where  $k = k(m, i)$ . Let  $f : [X_{\alpha+k,i}^i]^m \rightarrow S_n$ , where  $f(\nu) = s$  if  $\text{tp}_{\tau_\Phi}(\mathbf{a}_\nu) = s$ . Now by Lemma 4.3, there is a  $Y_{\alpha,i}$  (contained in  $X_{\alpha+k,i}^i \subset \bigcup_{j \leq i} P_j(M_\alpha)$ ) and with  $(Y_{\alpha,i}, <, <^*) \approx \leq^n \mu_\alpha$  and (4) is true on  $Y_{\alpha,i}$ . Denote  $Y_{\alpha,i}$  as  $X_{\alpha,i}^{i+1}$  and  $M_{\alpha+k}^i$  as  $M_\alpha^{i+1}$ . For  $j \geq i$ , let  $X_{\alpha,j}^{i+1}$  be the elements of  $X_{\alpha+k,j}^i$  that extend members of  $Y_{\alpha,i} = X_{\alpha,i}^{i+1}$ .  $\square_{4.8}$

We also refine (and rename for convenience) the index set of ordinals to guarantee that for all  $\alpha$ , each  $\tau^*$ -type in  $S_n$  is given the same truth value for all tuples from  $X_{\alpha,i}^i$  realizing  $r$ . This assignment gives us  $\Phi_{n+1}$ . We can do this because at any stage, the number of  $\Sigma_n$ -theories is at most  $2^{|T|}$  which is not cofinal in  $(2^{|T|})^+$ . Note that as  $i$  increases in this induction, the indiscernibility is being insured for larger  $\Sigma_i$ . Since the  $\Sigma_i$  are increasing this results in a consistent theory  $\Phi$  giving tree-indiscernibility in  $L(\tau_\Phi)$ .

At stage  $i$ , we have assigned to each  $\tau_i^*$  type  $r$ , a complete  $\Sigma_i$ -diagram in  $\tau_\Phi$ ; each formula  $\phi(\mathbf{v}) \in \Sigma_i$  has a fixed truth value for all  $\mathbf{c}_\eta$  where  $\eta$  realizes  $r$ . In particular, since all  $M_\alpha$  omit each  $\ell$ -type  $p \in \Gamma$  for any finite  $\ell$ , for each sequence of  $\ell$ -Skolem functions  $\mathbf{t}$  in a most  $m$ -variable, and each  $\eta$  realizing a  $\tau^*$ -type in  $m$ -variables there is a  $\phi_p \in \Sigma_{\ell \cdot m}$  with  $\phi_p \in p$  and  $\neg \phi_p(\mathbf{t}(\mathbf{c}_\eta))$ .  $\square_{4.7}$
